

An International Framework to Promote Access to Data

Peter Arzberger,^{1*} Peter Schroeder,² Anne Beaulieu,³ Geof Bowker,¹ Kathleen Casey,¹ Leif Laaksonen,⁴ David Moorman,⁵ Paul Uhler,⁶ Paul Wouters³

Recent national and multinational investments (1) in networking and continued gains in information technological capability (2) have given rise to a complex cyberinfrastructure that is rapidly increasing our ability to produce, manage, and use data (3). As research becomes increasingly global (4), data-intensive, and multifaceted (5, 6), it is imperative to address national and international data access and sharing issues systematically in a policy arena that transcends national jurisdictions. Open access to publicly funded data provides greater returns from the public investment in research, generates wealth through downstream commercialization of outputs, and provides decision-makers with facts needed to address complex, often transnational, problems. This article summarizes key findings of an international group that studied these issues on behalf of the Organisation for Economic Cooperation and Development (OECD) (7), which resulted in a ministerial-level declaration (8).

Legitimate restrictions on open access, and strong disincentives to sharing exist, based on concerns of protecting national security, privacy and confidentiality, intellectual property, and time-limited exclusive use by the scientific investigator. The lack of clear funding-agency policies in the face of strong competing interests, often far removed from academic research, poses problems for scientists in developing and developed countries and inhibit the advance of science for the public good. For example, research on cholera outbreaks and their relation to environmental factors (9) or on un-

OPERATING PRINCIPLES FOR DATA ACCESS REGIMES

- Openness
- Transparency and active data dissemination
- Assignment and assumption of formal responsibilities
- Technical and semantic interoperability of databases
- Quality control, data validation, authentication, and authorization
- Operational efficiency and flexibility
- Respect for intellectual property and other ethical and legal requirements
- Management accountability, including funding approaches

derstanding global climate change (10) requires access to data drawn from many disciplines and sources. This issue has been a topic of recent debate and its resolution is a high priority in many scientific and policy-making communities (11–17).

Analysis of these, and other examples (18), suggests that successful data access and sharing arrangements exhibit a number of key attributes and operating principles (see table, this page). Administrative and organizational management “domains” (see figure, this page) provide a framework for locating and analyzing where improvements can be made. Diversity in science suggests that a variety of institutional models and tailored data management approaches will be needed.

Establishing and maintaining this infrastructure requires continued and dedicated budgetary planning, with appropriate financial support. The use of research data cannot be maximized if access, management, and preservation costs (including cost of documentation and metadata creation) are an afterthought or are insufficiently or inconsistently funded in research projects (19). D. Atkins *et al.* (3) recommend that roughly one-third of the provisioning and operations of cyberinfrastructure and applications be used to support data repositories and digital libraries.

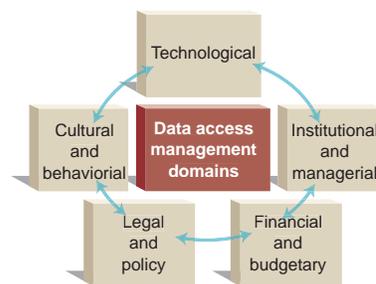

Appropriate professional and career reward structures are necessary (20–22). The way scientists are being evaluated and how their careers are shaped are at stake. For example, researchers who have spent years on building new databases, such as the Sloan Digital Sky Survey in astronomy, have effectively put their scientific careers on hold even though these databases are critical for the future development of the field. These considerations apply equally to those who produce, manage, and reuse research data.

At this point there is considerable heterogeneity in policies. In the United States, federal government databases are not copyright protected, whereas in the European Union government databases are eligible for protection under several database protection laws. Even within countries, different funding agencies have different stated policies; for example, in Canada, with three major science funding agencies, one follows the principles in the OECD declaration, one states access should not be a barrier, and a third has no policy (23). National laws and international agreements can directly affect data access and sharing practices.

At the last meeting of the OECD Committee for Scientific and Technological Policy (CSTP) at the ministerial level, ministers endorsed a declaration (8) based on the principle that research data from public funding should be openly available. Furthermore, they invited OECD to develop a set of guidelines based on commonly agreed principles (similar to those in the table) to facilitate optimal cost-effective access to digital research data from public funding. It

can be expected that these future guidelines will influence national and international regulation of research data, much as the OECD Guidelines on the Protection of Privacy (24), which have been a model for legislation all around the Western world.

Although the involvement of researchers in resolving these issues is critical, many scientists remain ignorant about existing policies at their institutions or nations, let alone those of other countries. To better inform future policies, several topics require further examination:

Domains of a data access regime.

1) Sharing of research data is far from a universal norm (25). What reward structures might lead to better access and sharing practices (26, 27)?

2) Scientific disciplines differ in their needs for data reuse. Increasingly, research questions demand access to data from different disciplines, and it can be difficult to use those data sets without sufficiently descriptive and understandable metadata. To what extent should data be made amenable to use in other areas of research or for other types of applications (19)?

3) Several studies (28–30) and recent reports (31, 32) have documented the beneficial effects of open access to public data on social and economic progress, at both the national and international levels. More empirical analyses would be very useful to help research-funding managers and policy-makers understand these issues better.

4) Various contractually based models of open community data sharing are emerging (33), as are international federated data management networks (13, 34). More study and experience with such approaches are needed, however, before they can be broadly implemented across national boundaries and disciplines.

5) Data access is particularly important in the international context of global issues such as health, environmental change, and food production, with particular challenges for data and researchers in developing countries. A systematic examination of barriers and best practices would document the current situation and offer guidelines for further action (35).

6) Public-private research collaborations in which partners have different motivations for producing data pose unique challenges for data policy and practice, for example, requiring access to data to validate published research. What are key principles to guide public policy in this mixed-mode funding of research?

Making data sharing and the principle of open access the default rule rather than the exception within the scientific community will be a significant step forward. Only with a sustained national and international effort, one that includes scientists, funding agencies, and other national and international bodies in the research enterprise, will the vision of using, analyzing, and synthesizing the vast amounts of data being produced by new technologies be realized.
